

# Interactive Visualization

Héctor Corrada Bravo

University of Maryland, College Park, USA

CMSC320: 2018-05-08

# Why Interactivity?

*Reduce data dimension:* allow user to explore large datasets by quickly switching between dimensions

*Overview first, zoom and filter, details on demand:* Provide big picture, let the user explore details as they desire

*Linked views for high dimensions:* There is a limit to the number of aesthetic mappings in a single graphic, make multiple graphics but link data objects between them

# Examples

*Politics:* [http://www.nytimes.com/interactive/2012/11/02/us/politics/paths-to-the-white-house.html?\\_r=0](http://www.nytimes.com/interactive/2012/11/02/us/politics/paths-to-the-white-house.html?_r=0)

*Movies:* <http://www.nytimes.com/interactive/2013/02/20/movies/among-the-oscar-contenders-a-host-of-connections.html>

*Sports:* <https://projects.fivethirtyeight.com/2018-march-madness-predictions/>

# Web-based interactive visualization

Take advantage of HTML document description and the **Document Object Model** interface to *bind* data to page elements.

- **Shiny**: bind data to controls
- **Data-driven Documents (d3.js)**: bind data to svg elements directly

# HTML and DOM

Web pages are structured using Hypertext Markup Language

```
<!DOCTYPE html>

<html>

  <head>

    <title>Page Title</title>

  </head>

  <body>

    <h1>Page Title</h1>

    <p>This is a really interesting paragraph.</p>

  </body>

</html>
```

# HTML and DOM

Web pages are structured using Hypertext Markup Language

```
<!DOCTYPE html>

<html>

  <head>

    <title>Page Title</title>

  </head>

  <body>

    <h1>Page Title</h1>

    <p>This is a really interesting paragraph.</p>

  </body>

</html>
```

# HTML and DOM

Web pages are structured using Hypertext Markup Language

```
<!DOCTYPE html>

<html>

  <head>

    <title>Page Title</title>

  </head>

  <body>

    <h1>Page Title</h1>

    <p>This is a really interesting paragraph.</p>

  </body>

</html>
```

# CSS

Cascading Style Sheets are used to style elements in the DOM.

```
body {  
    background-color: white;  
    color: black;  
}
```

# CSS

In general:

```
selectorA,  
selectorB,  
selectorC {  
    property1: value;  
    property2: value;  
    property3: value;  
}
```

# SVG

Scalable Vector Graphics (SVG) is special element used to create graphics with text.

```
<svg width="50" height="50">  
  <circle cx="25" cy="25" r="22" fill="blue" stroke="gray" stroke-width="2"/>  
</svg>
```

# SVG

Elements have *geometric* attributes and *style* attributes.

```
<circle cx="250" cy="25" r="25"/>
```

cx: x-coordinate of circle center

cy: y-coordinate of circle center

r: radius of circle

# SVG

Elements have *geometric* attributes and *style* attributes.

```
<rect x="0" y="0" width="500" height="50"/>
```

x: x-coordinate of left-top corner

y: y-coordinate of left-top corner

width, height: width and height of rectangle

# SVG

## *style* attributes

```
<circle cx="25" cy="25" r="22" fill="yellow" stroke="orange" stroke-width="5"/>
```

can be styled by class as well

```
svg .pumpkin {  
  fill: yellow;  
  
  stroke: orange;  
  
  stroke-width: 5;  
}
```

```
<circle cx="25" cy="25" r="22" class="pumpkin">
```

# Shiny and D3

Shiny: construct DOM and bind data (variables for example) to elements (a slide control for example) <http://shiny.rstudio.com>

D3: bind data to SVG element attributes (position, size, color, transparency, etc.) <http://d3js.org>

# Reactivity

Interactivity and binding in Shiny achieved using *reactive programming*.  
Where objects *react* to changes in other objects.

# Reactivity

Example:

```
shinyServer(function(input, output) {  
  output$plotOut <- renderPlot({  
    hist(faithful$eruptions, breaks = as.numeric(input$nBreaks))  
    if (input$individualObs)  
      rug(faithful$eruptions)  
  })  
  
  output$tableOut <- renderTable({  
    if (input$individualObs)  
      faithful  
    else  
      NULL  
  })  
})
```

# Reactivity

With intermediate objects:

```
fib <- function(n) ifelse(n<3, 1, fib(n-1)+fib(n-2))

shinyServer(function(input, output) {
  currentFib      <- reactive({ fib(as.numeric(input$n)) })

  output$nthValue  <- renderText({ currentFib() })
  output$nthValueInv <- renderText({ 1 / currentFib() })
})
```

Here is the new graph structure:

# Reactivity

A standard paradigm for interactive (event-driven) application development

A nice review paper: <http://dl.acm.org/citation.cfm?id=2501666>

# Binding data to graphical elements

With Shiny we can bind data objects to document elements.

More examples: <http://shiny.rstudio.com/gallery/>

We can also bind data directly to *graphical* elements since using SVG these are also document elements (D3).

# D3 Tutorial

Slides

# D3 Alternatives

- If you want to use a toolkit of standard charts based on d3: **NVD3**
- An alternative declarative library: **Vega**

# D3 and R

- We saw previously that D3 can access external data through json
- That's how we can pass data from R to the Javascript browser

# D3 and R

- **rCharts**: Most mature. Provides binding between R and a small set of javascript viz libraries.
- **ggvis**: Uses grammar of graphics like ggplot2, bindings to **Vega** to define JS charts.
- **htmlwidgets** a formalization of how to bind R to JS libraries.
- **Roll your own**
